

# Shipping & Fulfillment Policy

Lightweight operational context for the AI Analyst. Thresholds are analytical flags, not absolute service commitments.

## 1. Shipping days

- Shipping\_Days is defined as the calendar-day difference between Shipping\_Date and Order\_Date.
- The current Orders data has Shipping\_Days values from 1 to 30 days, with a median of approximately 15 days.
- Use calendar days consistently when comparing shipping performance.

## 2. Analytical flags

- Orders taking materially longer than the typical dataset pattern can be flagged for investigation.
- A shipping delay by itself should not be treated as evidence of poor profitability or poor customer experience.
- When investigating long shipping times, compare order volume, profit, sales and any available product/customer dimensions.

## 3. Suggested investigation bands

- 1–7 days: relatively fast shipment for this dataset.
- 8–15 days: typical-to-moderate shipment window.
- 16–23 days: slower shipment window worth monitoring.
- 24–30 days: extended shipment window and a useful candidate for investigation.
- These bands are analytical heuristics derived from the observed dataset distribution, not contractual service levels.

## 4. AI Analyst reasoning

- If a region, product or customer group has longer shipping times, compare its business performance before suggesting an operational issue.
- Do not claim that longer shipping caused lower sales or profit without supporting evidence.
